Applicant or Patentee: Rohit Sharma

Application or Patent No.: New Application

Filing Date or Issue Date: May 26, 2000

Title: Network Performance Monitoring and Restoration Based on Transmission Code Violations

I hereby declare that I am

the owner of the small business concern identified below:

an official of the small business concern empowered to act on behalf of the concern identified below:

NAME OF SMALL BUSINESS CONCERN Optical Networks, Incorporated

ADDRESS OF SMALL BUSINESS CONCERN 166B Baypointe Parkway

San Jose, CA 95134-1621

I hereby declare that the above identified small business concern qualifies as a small business concern as defined in 13 CFR 121.12, and reproduced in 37 CFR 1.9(d), for purposes of paying reduced fees to the United States Patent and Trademark Office, in that the number of employees of the concern, including those of its affiliates, does not exceed 500 persons. For purposes of this statement, (1) the number of employees of the business concern is the average over the previous fiscal year of the concern of the persons employed on a full-time, part-time or temporary basis during each of the pay periods of the fiscal year, and (2) concerns are affiliates of each other when either, directly or indirectly, one concern controls or has the power to control the other, or a third party or parties controls or has the power to control both.

I hereby declare that rights under contract or law have been conveyed to and remain with the small business concern identified above with regard to the invention described in:

the specification filed herewith with title as listed above.

the application identified above.

the patent identified above.

If the rights held by the above identified small business concern are not exclusive, each individual, concern or organization having rights in the invention must file separate verified statements averring to their status as small entities, and no rights to the invention are held by any person, other than the inventor, who would not qualify as an independent inventor under 37 CFR 1.9(c) if that person made the invention, or by any concern which would not qualify as a small business concern under 37 CFR 1.9(d), or a nonprofit organization under 37 CFR 1.9(e).

Each such person, concern or organization having any rights in the invention is listed below:

No such person, concern, or organization exists.

Each such person, concern or organization is listed below:

Separate verified statements are required from each named person, concern or organization having rights to the invention averring to their status as small entities. (37 CFR 1.27)

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 CFR 1.28(b))

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this verified statement is directed.

NETWORK PERFORMANCE MONITORING AND RESTORATION BASED ON TRANSMISSION CODE VIOLATIONS

Inventor: Rohit Sharma

5

CLAIM OF BENEFIT FROM PROVISIONAL APPLICATION

This application hereby claims the benefit under 35 U.S.C. § 119(e) of provisional patent application serial no. 60/136,624, entitled "Network Performance Monitoring and Restoration Based on Transmission Code Violations", filed on May 27, 1999, which provisional application is incorporated by reference herein in its entirety.

FIELD OF THE INVENTION

The present invention relates to the field of data and signal communications, and more particularly, to the use of transmission code violations to facilitate network monitoring and restoration.

BACKGROUND OF THE INVENTION

The reader is presumed to be familiar with commonly used communications network terminology and protocols. For general background information, the reader is referred to Roger L. Freeman, *Practical Data Communications*, John Wiley & Sons, New York, 1995, and the applicable networking standards published by standards bodies such as the Institute of Electrical and Electronic Engineers (IEEE) and the International Standards

Organization (ISO), and the Bellcore (now Telcordia) SONET Generic Requirement documents (GRs).

Modern data communication networks often include multiple links or data paths between two or more network elements depending on the network topology. These links are typically monitored for failure and performance degradation by a network management system using a network management protocol. The network management system monitors the network for failure or signal degradation and initiates restoration of the network by, for example, selecting a different physical link to carry the signal.

Depending on the transmission format, the performance of links in a network may be determined by: 1) the transmission signal power received at the monitoring network element, 2) the ability of the monitoring network element to recover bit or frame synchronization with the data stream, or 3) receipt of specific expected data patterns. For network elements using data patterns to monitor performance, the data patterns may be defined in an overall time division multiplexing (TDM) framing format such as Synchronous Optical Network (SONET), or as "hello" or "handshake" packets typically employed by packet-based data communications networks.

For networks using transmission codes (e.g., block codes), the rate that transmission code violations are received is another indication of the performance of a link. Transmission codes are typically used in communication systems to provide error detection and correction capability through the addition of systematic redundancy at the transmit end of a link such that errors caused by the transmission medium can be corrected at the receiver by means of a decoding algorithm. The amount of redundancy is typically dependent on the type of code selected and the level of error correction capability desired. Although many

modern networks use transmission code violations to provide error detection and correction, these conventional systems do not use transmission code violations to trigger network restoration and protection.

Accordingly, there is a need for a system and method of monitoring a network for transmission code violations, and to trigger network restoration and protection based on the number of transmission code violations. It is desired that such a system and method have low overhead and low cost so that it may be easily integrated into existing communications systems and network topologies.

SUMMARY OF THE INVENTION

A method of monitoring and restoring a communications network comprises the steps of: receiving a data stream encoded with a transmission code; decoding the data stream to determine a performance metric based on a number of transmission code violations; and restoring the performance of the communications network in response to the performance metric.

In a preferred embodiment of the present invention, the performance metric is an error rate determined from the number of transmission code violations, and the performance of the network is restored by transferring traffic from a first link to a second link in response to the performance metric exceeding a predetermined value.

A system for monitoring and restoring a communications network comprises a first network element and a second network element. The first network element generally includes a transmitter and a switch. The transmitter

generally includes an encoder coupled to receive a data stream. The encoder encodes the data stream with a transmission code (e.g., 8B/10B code). The switch is coupled to receive the encoded data stream from the transmitter and a switch signal from the second network element for switching the encoded data stream from a first link to a second link.

5 The second network element is coupled to the first network element via a plurality of links and generally includes a receiver having a decoder coupled to receive the encoded data stream from the first network element. The decoder decodes the encoded data stream and determines a number of transmission code violations. A monitoring module coupled to the decoder receives the number of transmission code violations and determines a performance metric based on the number of transmission code violations. The monitor module generates a switch signal if the performance metric exceeds a predetermined value. The switch signal is coupled to a switch in the first element for commanding the transfer of 15 the encoded data stream from a first link to a second link. Any number and combination of links and switches can be used with the present invention.

The present invention provides a low overheard, low cost system and method for providing network performance monitoring and restoration by taking advantage of the intrinsic structure of some common transmission codes 20 (e.g., 8B/10B). For example, the present invention does not require the

processing of an entire block of data to determine the health of a link. Rather, the present invention need only process a limited number of bits (depending upon the transmission code used) to determine the health of the link.

These and other features, aspects, and advantages of the present invention
5 will become better understood with regard to the following description,
appended claims, and accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a block diagram of a communications network.

10 Figure 2 is a block diagram of a point-to-point span of the communications network shown in Figure 1.

Figure 3 is a block diagram illustrating the functional elements of Gigabit Ethernet technology.

15 Figure 4 is a flow diagram of a method of monitoring and restoring the performance of the point-to-point span in Figure 2.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Although the following description of the present invention refers to 8B/10B data streams used in IEEE802.3z Gigabit Ethernet transmissions, other networking standards or protocols are equally applicable, including, without limitation 4B/5B transmission codes used in 100Mb/s Ethernet and FDDI, and
20 other modulation schemes which use extra code points (e.g., 5x5 QAM).

Referring to Figure 1, there is shown a block diagram of a communications network 100. Network 100 includes a plurality of interconnected network elements (NEs) 106, 108 and 110, coupled together by a plurality of data links L11, L12, L1N, L21, L22, L2N, as shown in Figure 1. Figure 1 makes clear that 5 network 100 may include any number of NEs interconnected in a variety of topologies, including, but not limited to, token ring, star, mesh, bus and other more complex topologies.

Network 100 includes spans 102 and 104. Span 102 includes NEs 106 and 108 coupled together by full-duplex links L11, L12, L1N and span 104 includes NEs 108 and 110 coupled together by full-duplex links L21, L22, L2N. NEs 106, 108, 110 can be, for example, bridges, routers, switches, hubs or any hybrids of such devices. In a preferred embodiment of the present invention, a data stream entering NE 108 on link L11 in span 102 is switched or otherwise routed by NE 108 from a working link L21 in span 104 to a protection link L22 in span 104 in 15 response to a switch signal generated by NE 110, which indicates failure or degraded performance in working link L21. The switch signal is generated in response to a performance metric based on a number transmission code violations detected by NE 110, as described further with respect to Figure 4.

Many standard communication protocols use transmission codes, such as 20 the 8B/10B transmission code described in A. X. Widmer and P. A. Franaszek, "A

DC-Balanced, Partitioned-Block, 8B/10B Transmission Code," IBM Journal of Research and Development, vol. 27, No. 5, pp. 440-451, September, 1983. The 8B/10B transmission code is a well-known forward error correction code (FEC) having two redundant bits (e.g., parity bits) for providing systematic redundancy 5 during encoding such that errors caused by the medium or link can be corrected at the receiver by means of a decoding algorithm.

In a preferred embodiment of the present invention, the error detection capability of the 8B/10B transmission code is used to initiate switching between two or more NEs, as described with respect to Figure 4. Although the description that follows refers to 8B/10B codes, other codes are equally applicable to the present invention, including but not limited to, 4B/5B code used in 100Mb/s Ethernet and FDDI or any other modulation schemes that use extra code points (e.g., 5x5 QAM).

Referring to Figure 2, there is shown a block diagram of a point-to-point 15 span 102 of the communications network 100 shown in Figure 1. In a preferred embodiment of the invention, span 102 is a Gigabit Ethernet (hereinafter also referred to as "GE"). GE technology is a 1-Gbit/sec (1,000-Mbit/sec) extension of the IEEE 802.3 Ethernet networking standard designed for applications needing a high-bandwidth backbone. It supports full-duplex operation for switch-to-switch 20 and switch-to-end connections and supports half-duplex operation on shared

network connections that use repeaters and the CSMA/CD medium access method. Figure 3 illustrates the functional elements of GE technology. Of particular importance to the present invention is the functional element relating to 8B/10B encoding and decoding. The 8B/10B coding function is part of the GE 5 standard and is well understood by those skilled in the art. For further information regarding GE technology, the reader is invited to review the IEEE 802.3z specification, which describes the GE technology.

In Figure 2, span 102 includes NE 106 and NE 108. NE 106 preferably includes an encoder 202, a transmitter 204, and a switch 206. NE 108 preferably includes a receiver 210, a decoder 212 and a monitor module 214. NEs 106 and 108 are coupled together by working link 216 and protection link 218. The monitor module 214 in NE 108 and switch 206 in NE 106 are coupled by a return link 220. Return link 220 can be a standby link reserved for traffic switched from a failed working link or links, or alternatively, it may be another working link.

15 NEs 106 and 108 would typically include both receiver and transmitter functionality (e.g., transceiver) for receiving and transmitting data, respectively, to other NEs in the network 100. For clarity, however, only the transmission functionality is shown for NE 106 and only the receiver functionality is shown for NE 108. In practice, encoder 202 and switch 206 can be integrated with 20 transmitter 204 and decoder 212 and monitor module 214 can be integrated with

receiver 210. Also, it is noted that the present invention can work with any number and combination of links, transmitters, receivers, switches and monitor modules depending on the network topology or system requirements.

Referring to NE 106, encoder 202 is coupled tone or more NEs for receiving 5 one or more data streams. Encoder 202 preferably encodes the data stream using, for example, an 8B/10B transmission code. The encoding of the data stream can be accomplished using the methods described in U.S. Patent No. 5,740,186, which is incorporated by reference herein in its entirety. Encoder 202 is coupled to transmitter 204 for formatting and placing the encoded data stream on either working link 216 or protection link 218 via switch 206. Switch 206 is coupled to return link 220 for receiving a switch signal from monitor module 214 located in NE 108. The switch signal is used by switch 206 to switch or otherwise transfer the encoded data stream from working link 216 to protection link 218, as further described with respect to Figure 4.

15 Referring to NE 108, receiver 210 receives the encoded data stream from the working link 216 and prepares the encoded data stream for decoding using conventional techniques. In one embodiment, receiver 210 is adapted to convert data link voltages to, for example, TTL/MOS compatible voltages for use with a phase locked loop coupled to a clock for generating a signal synchronized with 20 the data stream. The synchronized signal can be coupled to a logic sequencer

(not shown) in decoder 212 for recognizing frame or byte boundaries and for implementing a decoding algorithm compatible with the encoding algorithm to detect transmission code violations and provide error correction (See, e.g., U.S. Patent No. 5,740,186). Once decoder 212 has synchronized and decoded the 5 encoded data stream, module 214 counts a number of transmission code violations and computes a performance metric for link 216 based on the count. In a preferred embodiment of the present invention, the performance metric is a rate of transmission code violations R_E . The error rate R_E is computed by dividing the total number of transmission code violations occurring over a 10 predetermined period of time or, alternatively, over a predetermined number of data frames. If the performance metric indicates that the working link 216 has failed or provides unacceptably degraded performance, a switch signal is sent from module 214 to switch 206 via return path 220. Upon receipt of the switch signal from module 214, switch 206 switches or otherwise transfers the data 15 stream to protection link 218. A preferred embodiment of the switch 206 can include a multiplexer (not shown) coupled to a control module (not shown) for controlling the switching of traffic between links 216 and 218 in response to the switch signal using conventional techniques.

Although the embodiment described above could be used in scenarios 20 where the working link 216 has completely failed (e.g., break in the medium), the

present invention is equally applicable to scenarios where the working link is subject to degraded performance due to high noise levels or other types of interference, but has not completely failed. In such scenarios, link 218 is a working link used for carrying traffic during normal operation. The data stream 5 carried on link 216 can be multiplexed onto link 218 using a variety of techniques depending upon the application (e.g., time division multiplexing (TDM), frequency division multiplexing (FDM), wavelength division multiplexing (WDM)).

Referring to Figure 4, there is shown a flow diagram of a method of monitoring and restoring the performance of a communication link in accordance with the present invention. In span 102 forming part of network 100, NE 106 transmits a data stream encoded with a transmission code (e.g., 8B/10B) over working link 216. NE 108 receives 400 the encoded data stream from working link 216. The data stream is synchronized 402 by receiver 210 and decoded 404 by decoder 212 in NE 108 using conventional techniques. Decoder 212 counts 15 406 a number of transmission code violations using known methods (see, e.g., U.S. Patent No. 5,704,186). Monitor module 214 in NE 108 determines a performance metric (e.g., error rate R_E) from the number of transmission code violations. If 410 the performance metric exceeds a predetermined value, a 20 switch signal is generated 412 by monitor module 214 for commanding switch

206 in NE 106 to switch the encoded data stream from working link 216 to protection link 218.

The preferred embodiment of the present invention described above, provides a low overheard, low cost system and method for providing network 5 performance monitoring and restoration by taking advantage of the intrinsic structure of some common transmission codes (e.g., 8B/10B). For example, the preferred embodiment does not require the processing of an entire block of data to determine the health of a link. Rather, the preferred embodiment need only process a limited number of bits (depending upon the transmission code used) to determine the health of the link.

The foregoing description of the embodiments of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above teaching. It is 15 intended that the scope of the invention be limited not by this detailed description but rather by the claims appended hereto.

What is claimed is:

1 1. A method of monitoring and restoring a communications network,
2 comprising the steps of:
3 receiving a data stream encoded with a transmission code;
4 decoding the data stream to determine a performance metric based
5 on a number of transmission code violations; and
6 restoring the performance of the network in response to the
7 performance metric.

1 2. The method of claim 1, including the step of:
2 generating an error rate based on the number of transmission code
3 violations for use as the performance metric.

1 3. The method of claim 1, including the step of:
2 generating a switch signal in response to the performance metric
3 exceeding a predetermined value.

1 4. The method of claim 3, including the step of:
2 transferring the data stream from a first link to a second link in
3 response to the switch signal.

1 5. The method of claim 2, wherein the step of generating an error rate
2 includes the step of:
3 dividing a number of transmission code violations by a
4 predetermined period of time.

1 6. The method of claim 2, wherein the step of generating an error rate
2 includes the step of:

dividing a number of transmission code violations by a predetermined number of data frames.

1 7. A system for monitoring and restoring a communications network,
2 comprising:

a first network element, comprising:

a transmitter having an encoder coupled to receive a data stream, the encoder for encoding the data stream with a transmission code;

a switch coupled to receive the encoded data stream from the transmitter, the switch coupled to a switch signal for switching the encoded data stream from a first link to a second link;

a second network element coupled to the first network element via the first and second links, comprising:

a receiver having a decoder coupled to receive the encoded data stream from the first network element, the decoder for decoding the encoded data stream and determining a number of transmission code violations; and

a monitoring module coupled to receive the number of transmission code violations from the receiver, the monitor module for determining a performance metric based on the number of transmission code violations, and for providing a switch signal to the switch in the first network element if the performance metric exceeds a predetermined value.

- 1 8. The system of claim 7, wherein the performance metric is an error rate
- 2 determined from the number of transmission code violations.
- 1 9. The system of claim 7, wherein the transmission code is an 8B/10B code.
- 1 10. The system of claim 7, wherein the transmission code is an 4B/5B code.
- 1 11. The system of claim 7, wherein the communications network is a Gigabit
- 2 Ethernet.
- 1 12. The system of claim 7, wherein the switch signal is coupled to a third
- 2 network element in a second communications network.

**NETWORK PERFORMANCE MONITORING AND RESTORATION
BASED ON TRANSMISSION CODE VIOLATIONS**

ABSTRACT OF THE DISCLOSURE

5 A network element (NE) in a communications network decodes a data stream received over a communication link. Upon synchronization with the data stream, the NE determines a performance metric for the link based on a number of transmission code violations. In response to the performance metric exceeding a predetermined threshold, the NE commands the selection of a different link to carry the data stream via a switch signal. The switching or rerouting of signals may occur between a single pair of NEs (e.g., point-to-point span) or in a more complex topology having a plurality of interconnected NEs.
